Abstract

The growth of sales business actors is increasing, so there is a need to predict sales levels for future sales so as not to experience financial losses. This research aims to obtain an accurate sales-level prediction model. The seller will understand the important features that influence the level or value of sales. The method used in this research is the Machine Learning (ML) regression algorithm, which uses hyperparameter tuning. The preprocessing stage in this research is very important to produce better prediction values. This research produced the best algorithm, namely XGBoost, with a Root Mean Squared Error (RMSE) result of 968 and a Mean Absolute Error (MAE) value of 713. These results are better than those of previous research using the same XGBoost algorithm but not optional tuning hyperparameters, namely RMSE of 1052 and MAE of 739.03. So by using optuna tuning hyperparameters you can reduce the error value of the prediction results.

Keywords : Predictions, Sales, Hyperparameters, Optuna, XGBoost

Abstrak

Pertumbuhan pelaku bisnis penjualan semakin meningkat, untuk itu perlu adanya suatu prediksi terhadap tingkat penjualan untuk penjualan masa depan agar tidak mengalami kerugian finansial. Tujuan dari penelitian ini adalah untuk mendapatkan model prediksi tingkat penjualan dengan akurat. Pihak penjual akan memahami fitur-fitur penting yang mempengaruhi terhadap tingkat atau nilai penjualan. Metode yang digunakan dalam peneltiian ini adalah algoritma regression *Machine Learning (ML)* serta menggunakan *hyperparameter tuning*. Tahap *preprocessing* dalam penelitian ini sangat penting untuk dapat menghasilkan nilai prediksi yang lebih baik. Hasil dari penelitian ini menghasilkan algoritma terbaik yaitu XGBoost dengan hasil *Root Mean Squared Error (RMSE)* adalah 968 dan nilai *Mean Absolute Error (MAE)* adalah 713, hasil tersebut lebih baik dari hasil penelitian sebelumnya dengan menggunalan algoritma yang sama yaitu *XGBoost* tetapi tidak menggunakan *hyperparameter tuning optuna* menghasilkan nilai *RMSE* sebesar 1052, dan *MAE* sebesar 739.03. Sehingga dengan menggunakan *hyperparameter tuning optuna* dapat menurunkan nilai *error* hasil prediksi.

Kata Kunci : Prediksi, Penjualan, Hyperparameter, Optuna, XGBoost

1. INTRODUCTION

A period of transformation supported by digitalization, information, communication technology, and artificial intelligence has resulted in rapid technological developments [1]. Increasingly sophisticated technology can be helpful in various fields, such as business and economics, resulting in many researchers arguing that increasingly sophisticated technology will usher in a new era [1]. In the field of business and economics, sales activities are undoubtedly inseparable. Sales is an action carried out by a company or retail store to

ISSN. 2620-6900 (Online) 2620-6897 (Cetak)

maintain its business so that it continues to grow and obtain the desired profits. Therefore, to maintain maximum profits, an accurate prediction of the level or value of sales needs to be made [2].

Some retail stores still use simple technology, such as Microsoft Excel, to estimate sales, sometimes based only on the leader's wishes and only on expected estimates [1]. Sellers will need data regarding demand for products currently on the market to decide whether to increase or decrease the number of product units. Business people will constantly improve sound quality to satisfy consumers with the products or goods they buy. Business people will also compete in the market for the products or goods they own. If a business competes in the market without considering principles, then the business will be at risk of experiencing financial losses.

With sophisticated technology, it can enable companies to carry out accurate sales level prediction analysis. A business company needs to have the ability to estimate product sales. Accurate predictions or forecasting can help businesses in companies maximize investment, reduce inventory costs, increase sales and profitability, and avoid danger [3]. With accurate predictions about how sales will be in the future, business growth can be adequately managed and will have fatal consequences for sales [3]. Prediction is an action to predict circumstances or conditions for the future by testing past data. Sales prediction is a forecast of future sales based on past sales that occurred [4]. By predicting the level or value of sales, companies can make reliable and appropriate decisions and optimize their business resources. The advantage of business companies in making predictions on product sales data is that they can determine the current level of demand for services or products in the market and future demand for products needed by customers.

Predicting the level or value of sales cannot be done just like that, and experts are needed. That is, they need to pay attention to the features that influence it, such as product type, price, type of shop, location, etc. Therefore, predicting the level or value of sales is influenced by many features. However, these features still need sufficient support in predicting sales, so a prediction model for the level or value of sales is needed accurately based on existing features.

This research will concentrate on forecasting the level or value of sales in a store. Product level or value hypotheses impact sales, such as brand, price, visibility, and so on, while store hypotheses, such as city type, store capacity, location, etc.

There needs to be a detector regarding the level or value of product sales in a shop. One prediction method that is widely used and is considered to be more effective and efficient than others is Machine Learning (ML). Another method that can be used apart from ML is statistical or traditional methods. Still, this method requires a lot of time and is expensive, whereas using a statistical approach focuses on traditional mathematical methods. The difference between using ML and statistical methods is that methods using statistics are more rigid, while using ML can adapt to the problem to be detected. ML algorithms are currently widely used by large companies worldwide for predictions. A collection of statistical methods known as ML is the science of developing algorithms and statistical models for computer systems that can be used to create complex applications that can accurately classify and predict various types of data [3]. ML is a branch of artificial intelligence (AI) that is useful for creating models [5]. ML is also a technique or method used to learn extensive data and help make predictions [6]. ML learns from data distribution to make judgments about incoming data. The model or classifier can determine sales predictions based on the input features. The various processing methods provided by Machine Learning ML can be used effectively and affordably to forecast future sales. These ML algorithms are categorized into Reinforcement, Unsupervised, Semi-Supervised, and Supervised Learning [7]. ML works in three main parts: the decision-making process, error function, and model optimization process.

To increase the accuracy of ML results, you can use hyperparameter tuning to get the best parameters so that model accuracy increases. Hyperparameter tuning is finding the best set of hyperparameters from an ML model to get the maximum evaluation score [8]. One hyperparameter tuning that is relatively new and compared advantages to other has hyperparameter tuning is optuna hyperparameter tuning. Optuna is а hyperparameter tuning software framework specifically designed for machine learning, which is helpful in efficiently optimizing and finding more effective hyperparameters. It also has a pruning strategy to save computing resources and time [9].

Several researchers have researched sales predictions using ML. G. Beher and N. Nain 2020 researched sales forecasting or predictions using ML algorithms, namely Linear Regression, Decision Tree, Ridge Regression, XGBoost with Mean Absolute Error (MAE) and Root Mean Squared Error (RMSE) matrices to measure model performance and the value obtained is that the XGBoost model outperforms other methods where XGBoost obtains the lowest error value, namely the RMSE value is 1052 [10]. This research will become the primary reference for the research carried out. It is hoped that the results of this research will provide benefits to help accurately predict product level sales or product value in a store, thereby producing better accuracy values and reducing the risk of financial loss.

2. RESEARCH METHODOLOGY

2.1. Research Flow Scheme

Several stages were carried out in this research. These steps can be depicted in Figure 1 as follows:

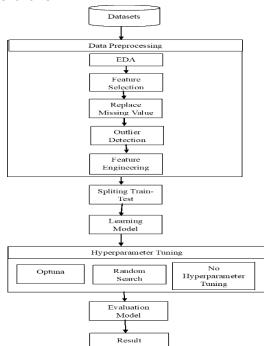

Figure 1. Research Methodology

2.2. Data Collection

In this research, data collection was carried out by searching for data secondaryly, namely publicly. The public data taken is data regarding product sales at Big Mart stores. This public data was taken from the online site at https://www.kaggle.com/datasets/brijbhushan nanda1979/bigmart-sales-data/data. Product sales data at Big Mart stores consists of 12 attributes, 8523 train data, and 5681 test data.

2.3. Data Preprocessing

There are several stages in the data preprocessing process carried out in this research. Namely, the first stage is the Exploratory Data Analysis (EDA) process. EDA is a process carried out in data preprocessing that is applicable to help produce analysis results that help find patterns in data [11]. Then, the feature selection process, replacement of missing values, and feature engineering are carried out. The stages in the preprocessing process are carried out to provide convenience in the training data experimentation process to produce better model predictions. They can provide prediction results with smaller model error values.

2.4. Feature Selection

The process after EDA data preprocessing is to carry out feature selection. In this process, choosing what features will be used in the prediction process is helpful because not all features are relevant to the problem at hand. If these features are still used, they will affect the prediction results, so it is necessary to select existing features and lacking features. Influential should be removed [12]. The feature selection used in this research is using a correlation matrix. Matrix correlation functions to investigate the relationships that exist between numerical variables in a dataset [13].

2.5. Replace Missing Value

The replace missing value stage is the stage where the data contains NaN or empty values. Therefore, it is necessary to fill in NaN values in the empty attributes [14]. Attributes with missing values or NaN are not removed because they are a better choice. After all, data is wellspent.

2.6. Outlier Detection

Outlier detection will try to catch cases showing significant deviations from the existing majority pattern [15]. The outlier detection process is a process that is not easy to carry out because not all existing values are identified as outliers, so a statistical method is needed to identify and eliminate data that is in the abnormal range in the data set.

2.7. Feature Engineering

Feature engineering is necessary because the features in the data greatly influence the model performance results [16]. In the engineering process, an engineering process is carried out on several features in the dataset, namely the item_fat_content attribute because this attribute

has upper and lower case letters, so it needs to be combined and added categories to item_fat_content, namely non-edible. Label encoding is carried out in the outle_size, item_fat_content, outlet type, and outlet_location_type attributes, namely, changing non-numerical data into numeric value data. In the item_identifier attribute, the attribute is changed to item_identifier_categories, and products are categorized into three categories: food, drinks, and non-consumable goods [10]. Then, one hot encoding process will be carried out on the item_type, item_identifier_categories, and outlet_identifier tables.

2.8. Splitting Train-Test

At the splitting train and test stage, the data is divided into two parts based on the split selected as training data and the rest as testing data. Train data functions to fit the model in the ML process, while test data functions to evaluate the results of the fit model in the ML [17]. The split used in this research is 80:20.

2.9. Learning Model

After going through the data preprocessing process and splitting, the dataset is tested using an ML algorithm at the learning model stage.

2.10.Evaluation Model

After the testing process uses the ML algorithm, it will produce a prediction value, namely displaying the error value. The method for displaying the error value uses evaluation methods, namely RMSE, MAE, R2 Score, CV Score Mean, and Std.

2.11.Results

After experiments and trials, the best model will be produced, with the smallest error value obtained compared to reference research.

3. RESULTS AND DISCUSSION

In this research, several experiments were carried out, namely as follows:

3.1 ML Algorithm

In the first experiment, ML algorithm experiments were carried out without hyperparameter tuning, and no outlier detection process was carried out during data preprocessing. The following are the results of using the ML algorithm without hyperparameter tuning and without outlier detection in the data preprocessing process, which can be seen in Table 1.

The first experiment using a regression algorithm from 15 ML algorithms without using hyperparameter tuning and without carrying out an outlier detection stage during preprocessing, produced relatively high error values, namely an average RMSE value above 1100, an average MAE value above 780, an average R2 value -average produces a value close to 1. Each algorithm's mean CV Score value is still above 1000, while the CV Score Std value has a reasonably high error value above 35.

In the second experiment, experiments were carried out using the ML algorithm, namely the regression algorithm, and hyperparameter tuning using random search without outlier detection. The results of the second experiment produced the lowest error value obtained by the extra trees regressor algorithm. However, the error value was still very high. Namely, the average error value of the 15 algorithms used, namely the RMSE error value, was still above 1000; therefore, it was necessary to try again.

TABLE III. ML ALGORITHM+HYPERPARAMETERTUNING OPTUNA TEST RESULTS

In the third experiment, experiments were carried out using the ML algorithm, namely the regression algorithm used, and hyperparameter tuning was carried out using Optuna without outlier detection. The results of the third experiment produced relatively high error values. The results of the third experiment showed that the best algorithm was a random forest regressor. However, the error value was still high, namely the RMSE value above 1000; for this reason, it was necessary to test again.

In the fourth experiment, experiments were carried out using the ML algorithm, namely the regression algorithm, and in the preprocessing process, the outlier detection stage was carried out. The results of the fourth experiment produced better values. Namely, the error value decreased compared to the previous experiment. So, by detecting outliers in the dataset, you can improve the results of the ML algorithm.

TABLE V. ML ALGORITHM+ HYPERPARAMETER TUNING RANDOM SEARCH+DETEKSI OUTLIER TEST RESULTS

The fifth experiment produced quite good values when the fifth experiment used hyperparameter tuning random search and added an outlier detection process during the preprocessing process. However, when using random search hyperparameter tuning, the SVR algorithm experienced a decrease.

In the sixth experiment, the ML algorithm uses optuna hyperparameter tuning and an outlier detection process is carried out during data preprocessing. There is a pretty good decrease in the error value compared to the fifth experiment, where the sixth experiment produces the algorithm with the lowest error value, namely the XGBoost algorithm. The error value in the XGBoost algorithm decreased by 15 in the RMSE value, and the MAE error value decreased by 9, while the R2 value also improved, namely 0.576, and the CV Score mean and Std values were also better than in the fifth experiment.

After generating predicted values using the R2, MAE, RMSE, CV Score Mean, and Std evaluation matrices from each ML algorithm with six trials, it was found that XGBoost Regressor obtained the best algorithm with optuna hyperparameter tuning and when the outlier detection process was carried out during the data preprocessing process.

The research results produced an RMSE value of 968 and an MAE value of 713, and this shows that the research results showed that the RMSE error value decreased by 84 and the MAE value decreased by 26.03 from the reference paper.

TABLE VII. PREDICTION OF RESULTS USING THE REFERENCE MODEL

Nama	RMSE	MAE
ML Algorithm		
+ <i>Optuna</i> +Outlier		
Detection	968	713
Reference Paper	1052	739.03

From several experiments that have been carried out on several ML algorithms, it was found that the best results used to predict the level/value of product sales in stores were experiments with the XGBoost Regressor algorithm using Optuna hyperparameter tuning with outlier detection producing quite good error values compared to the reference paper. That is, it produces an RMSE error value of 968, reducing the error value by 84.

Figure 2 below shows several examples of predictions of sales levels or values using Big Mart sales data.

Outlet_Type Outlet_Size Item_Weight Item_Fat_Content Outlet_Location_Type Outlet_Age Item_Outlet_Sales

	ounce_type	ounce_one	real_reaging	item rate content	ounce_cocuron_type	ouneringe	nem_ounce_ourco
0	1	2	20.750000	0	0	25	1641.148926
1	1	2	8.300000	2	1	17	1428.293579
2	0	2	14.600000	1	2	26	821.942139
3	1	2	7.315000	0	1	17	2456.098633
4	3	2	12.857645	2	2	39	4405.342773

Figure 2. Prediction Of Product Sales Levels

The results of the prediction of the level or value of product sales, where from the 5 examples of predicted data, the outlet_type, which is a grocery store type in the table, has a value of 0, has the lowest sales value compared to supermarket type, stores, even though the store is old. Meanwhile, sales in supermarkets are higher, and even though the size of the shop is medium, sales are still significant. This is due to one of the shop locations, where residents in tier 3 prefer supermarkets to grocery shops.

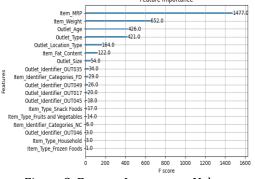

Figure 3. Feature Importance Value

Figure 3 shows the value of feature importance using the XGBoost algorithm model with optuna tuning hyperparameters because it has the lowest prediction error value. The results of the feature importance value show that the item_MRP attribute is the highest. This shows that the item_MRP attribute has the most influence on predicting a store's value or level of product sales. Then, continue with item_weight, the second most influential attribute in predicting sales level or value. Other influential outlet age. attributes are outlet type, outlet_location_type, item_fat_content, outlet_size, outlet_identifier, item_identifier, and item_type.

4. Conclusions and Suggestions

The choice of ML algorithm determines the results of good predictions from existing data and is also determined by the parameters used. Optuna hyperparameter tuning can reduce the error value in the XGboost regressor algorithm and is the best algorithm result compared to 15 other experimental algorithms. Outlier detection in the preprocessing process can improve the results of the ML algorithm. Evaluation results from research that has been carried out using the metrics RMSE, MAE, R2, CV Score Mean, and Std show that by using an ML algorithm model with optimal hyperparameter tuning and carrying out an appropriate preprocessing process, namely by carrying out outlier detection, it is possible to find a model with the correct error value-decreased compared to algorithm experiments without outlier detection. The influential features from the research results that have been carried out are the item_MRP, item_weight, outlet_age, and outlet_type features. So, the value or level of product sales is influenced by the product's retail price.

The suggestions from this research are to readjust each parameter of the ML algorithm used to improve the performance of the best algorithm in predicting the level or value of product sales in stores and develop the use of other data preprocessing processes, such as for handling outlier data, and also carry out the development of feature selection in selecting attributes that have a strong influence on the algorithm model used and do not reduce the results of the algorithm used, as well as carry out further development of the use of hyperparameter tuning to improve the results of the algorithm used.

5. ACKNOWLEDGMENTS

The author takes this opportunity to thank the Chancellor of Nusa Mandiri University, Mrs Prof. Dr Dwiza Riana, S.Si, MM, M.Kom, Deputy Chancellor of Nusa Mandiri University, Head of the Computer Science Study Program at Nusa Mandiri University, Mr Dr Muhamad Haris, M.Eng as the thesis supervisor, his beloved parents and older siblings always provide both material and moral support to the author and all parties who cannot be mentioned one by one.
